Worst case scenario is that you might have to swap out the hard drive in to another Pc. It worked for me one time. I just booted it up as a slave and backed up everything on the drive. That way everything is safe. just remember to boot the right drive.

I still couldn't get it working later, so i swapped it out again and this time i deleted the windows folder on that drive. I put the drive back and set up windows again from scratch, this isn't ideal, since you have clean up all the old software by hand, and this can take a while.

If it is the mother board that has been passworded, you can discharge to memory, check your documentation for your mobo or dl a pdf from the makers. It isn't hard to do, but be careful!

I don't know how to kill the password for windows.

Hay I think i have more then 200 posts :rolleyes:
